Evidence that travels with the objects

np-FDOs make data, claims, decisions and approvals self-describing and provenance-bearing.

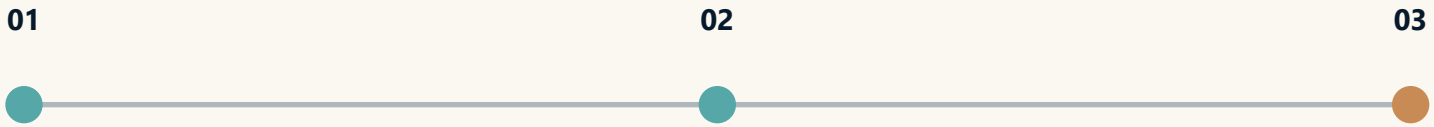

Evidence is carried by the objects themselves.

The evidentiary barrier to AI adoption

For the adoption of AI in regulated environments, the binding constraint is evidentiary, not model-level.

An organisation cannot act on an AI output it cannot account for.

where the input came from

what transformed it

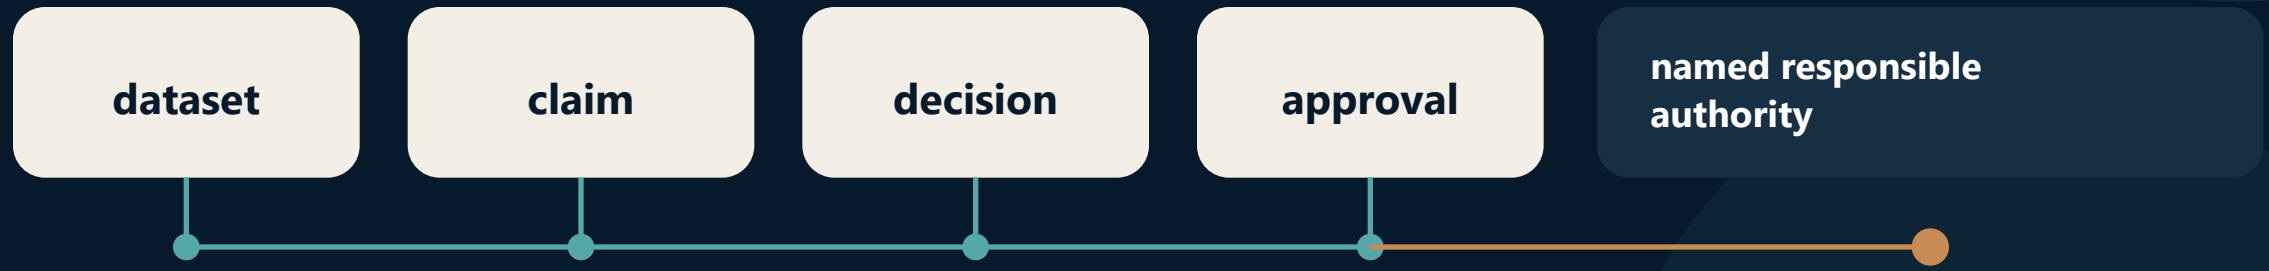

who stands behind the result

Accountability requires evidence of all three.

Better models do not produce that evidence. FAIR does.

np-FDOs: self-describing, provenance-bearing FAIR Digital Objects

np-FDOs, FAIR Digital Objects based on nanopublications, make every dataset, claim, decision and approval self-describing, resolvable and provenance-bearing.

The provenance chain ends at a named responsible authority.

A regulator, auditor or counterparty can traverse that chain without the underlying data leaving the organisation that holds it.
